

Regex filter voor studenten namen.

De onderstaande code laat de implementatie van de regex filter zien.

```

Fix voor MongoDB excel export dynamic field names

De onderstaande code is een stukje van de code voor de namen uit de mongodb te pullen en te weergeven in de excel export

```
    for item in collection:
    ]
cleaned_collections.append(cleaned)
```

Rename foreign keys to their corresponding names for better readability in the Excel file

```
for project in cleaned_collections[8]:
    researcher_id = project.get("researcher")
    if researcher_id:
        researcher = db.researchers.find_one({"_id": ObjectId(researcher_id)})
        if researcher:
            project["researcher"] = researcher.get("name", "")

    research_id = project.get("research_project")
    if research_id:
        research_project = db.research_projects.find_one({"_id": ObjectId(research_id)})
        if research_project:
            project["research_project"] = research_project.get("research_project", "")

    course_id = project.get("course")
    if course_id:
        course = db.course.find_one({"_id": ObjectId(course_id)})
        if course:
            project["course"] = course.get("name", "")

    projects_id = project.get("projects")
    if projects_id:
        projects = db.projects.find_one({"_id": ObjectId(projects_id)})
        if projects:
            project["projects"] = projects.get("title", "")
```

Rename dynamic field columns to their corresponding names for better readability in the Excel file

```
for collection in cleaned_collections:
    for item in collection:
        for key in list(item.keys()):
            if key.startswith("dynamic_"):
                dynamic_field_id = key.split("_")[-1]
                dynamic_field = db.configurations.find_one({"_id": ObjectId(dynamic_field_id)})
                if dynamic_field: # If the dynamic field exists, rename the key to the field name
                    new_key = dynamic_field.get("name", key)
                    item[new_key] = item.pop(key)
```

Bug gerelateerd aan array field removal.

Bugged code voor die er voor zorgde dat 2 entrees werde geremoved inplaats van 1

```
document.getElementById('add_array_field').addEventListener('click', function() {
    var container = document.createElement('div');
    var input = document.createElement('input');
    input.type = 'text';
    input.name = 'array_contents[]';
    input.required = true; // Set required for new array fields
    container.appendChild(input);
    var lineBreak = document.createElement('br');
    container.appendChild(lineBreak);
    document.getElementById('array_contents_container').appendChild(container);
});

document.getElementById('remove_array_field').addEventListener('click', function() {
    var container = document.getElementById('array_contents_container');
    if (container.childElementCount > 1) { // Ensure at least one input remains
        container.removeChild(container.lastElementChild); // Remove <br>
        container.removeChild(container.lastElementChild); // Remove <input>
    }
});
```

De werkende code. Doordat de break en de code in een child werden gezet removede de remove br beide de input en de br waardoor de remove input ook de voorgaande input verwijderde.

```
document.getElementById('remove_array_field').addEventListener('click', function() {
    var container = document.getElementById('array_contents_container');
    if (container.childElementCount > 1) {
        container.removeChild(container.lastElementChild); // Remove <br>
        container.removeChild(container.lastElementChild); // Remove <input>
    }
    var inputs = container.querySelectorAll('input[type="text"]');
    if (inputs.length > 1) {
        container.removeChild(inputs[inputs.length - 1]);
        container.removeChild(container.lastElementChild); // Removes <br>
    }
});
```
